

arm64 qemu crash工具使用流程

2024年8月24日 10:10

Author: 茆寒

date: 2022.8.24

编译内核:

如果crash工具里gdb版本不高, 7.3.0工具的gdb版本低, crash时候会报错误, 需要指定编译:
make KCFLAGS="-gdwarf-4" -j16

启动qemu:

```
qemu-system-aarch64 \
-M virt \
-cpu cortex-a57 \
-smp 1 \
-m 512M \
-kernel /home/maohan/linux/kernel/qemu-k54/qemu-k54/arch/arm64/boot/Image \
-nographic \
--append "noinitrd root=/dev/vda rw nokaslr console=ttyAMA0 loglevel=8" \
-drive if=none,file=rootfs_ext4.img,id=hd0 \
-device virtio-blk-device,drive=hd0 \
-netdev user,id=eth0 \
-device virtio-net-device,netdev=eth0 \
-fsdev local,security_model=passthrough,id=fsdev0,path=/home/maohan/linux/kernel/qemu-learn/image \
-device virtio-9p-device,id=fs0,fsdev=fsdev0,mount_tag=hostshare \
```

注: 上面两行-fsdev是共享目录, 用来传文件

参数解释:

kaslr是内核启动随机地址, vmlinux的内核地址是固定的, 所以gdb调试时候要关掉, 方法:

- 1、是重新编译内核, 在arch/arm64/configs/defconfig 中将CONFIG_RANDOMIZE_BASE=y修改成CONFIG_RANDOMIZE_BASE=n
- 2、qemu启动的cmdline中增加nokaslr 参数, 通过参数方式关闭

启动虚拟机之后:

```
echo 1 > /proc/sys/kernel/panic_on_oops 设置panic不重启
echo c > /proc/sysrq-trigger 触发dump
按ctrl + a c打开QEMU控制台, 使用以下命令导出vmcore:
(qemu) dump-guest-memory /your_path/vmcore
(qemu) dump-guest-memory -z /your_path/vmcore # 压缩, 导出vmcore
```

安装crash工具:

网站: [git://github.com/crash-utility/crash.git](https://github.com/crash-utility/crash.git)

我下载的: 为了兼容kernel5.4

crash-7.3.0

crash-7.2.9 -> crash-7.3.0
Signed-off-by: Kacuhito Hagio <k-hagio@nec.com>

安装: 解压之后进入文件夹

make target=ARM64

strip -s crash ==》清除掉多余符号, 把crash文件复制到自己的coredump文件夹

如果安装8.0.5版本可能make时候会出现:

```
rm -rf $Backupdir; exit $rc
/home/maohan/tools/crash-8.0.5/gdb-10.2/missing: 01: makeinfo: not found
WARNING: 'makeinfo' is missing on your system.
You should only need it if you modified a '.text' file, or
any other file indirectly affecting the aspect of the manual.
You might want to install the Texinfo package:
<http://www.gnu.org/software/texinfo/>
The spurious makeinfo call might also be the consequence of
using a buggy 'make' (AIX, DU, IRIX), in which case you might
want to install GNU make:
<http://www.gnu.org/software/make/>
make[5]: *** [Makefile:542: bfd.info] 错误 127
make[4]: *** [Makefile:1654: info-recursive] 错误 1
make[3]: *** [Makefile:2771: all-bfd] 错误 2
make[2]: *** [Makefile:800: all] 错误 2

crash build failed

make[1]: *** [Makefile:263: gdb_merge] 错误 1
make: *** [Makefile:254: all] 错误 2
```

需要更新: sudo apt-get install libaio-dev libncurses5-dev zlib1g-dev liblzma-dev flex bison byacc

需要安装: sudo apt-get install texinfo

启动crash工具进行分析:

把vmlinux和vmcore和crash工具放到一起:

```
./crash vmcore vmlinux -m vabits_actual=48 -m kimage_voffset=0xffff7fffd0000000
./crash803 vmcore vmlinux -m vabits_actual=48 -m kimage_voffset=0xffff7fffd0000000
```

使用gcc-linaro-13.0.0-2022.11-x86_64-aarch64-linux-gnu编译的kernel 启动crash会出现错误: crash neither runqueue nor rq structures exist, 换成gcc-arm-8.3-2019.03-x86_64-aarch64-linux-gnu编译的就ok了

vabits_actual通过查看:

虚拟地址长度可以在.config中查看 (64位平台通常的配置是48或者39):

```
//CONFIG_ARM64_VA_BITS_48=y CONFIG_ARM64_VA_BITS=48
```

```
CONFIG_ARM64_4K_PAGES=y
# CONFIG_ARM64_16K_PAGES is not set
# CONFIG_ARM64_64K_PAGES is not set
# CONFIG_ARM64_VA_BITS_39 is not set
CONFIG_ARM64_VA_BITS_48=y
CONFIG_ARM64_VA_BITS=48
CONFIG_ARM64_PA_BITS_48=y
CONFIG_ARM64_PA_BITS=48
# CONFIG_ARM64_PA_BITS_39 is not set
```

kimage_voffset可以通过GDB单步调试获取: <https://zhuanlan.zhihu.com/p/667555796>

首先在qemu启动时候加上-s -S

```
qemu-system-aarch64 \
-machine virt,virtualization=true,gic-version=3 \
-nographic \
-m size=1024M \
-cpu cortex-a72 \
-smp 2 \
-kernel Image \
-drive format=raw,file=rootfs.img \
-append "root=/dev/vda rw" \
-s \
-S
```

-s 是-gdb tcp::1234 的简写, 如果需要换端口可以用-gdb tcp::1234替换-s参数

-S 是freeze cpu at startup的指令, 也就是kernel 启动时就挂起, 等待调试连接, 如果不需要调试内可以去掉

GDB单步调试找到镜像虚拟地址: <https://blog.csdn.net/tanxjian/article/details/121889366>

先安装arm64能用的gdb (貌似arm32的也能用):

```
apt-get install gdb-multiarch
```

注: p /x kimage_voffset会出现: no debugging symbols found的报错, 是因为.config里CONFIG_DEBUG_INFO没开, 编译kernel时候会有[Y/N]的提示, 全打开来

启动qemu之后再另开一个终端:

```
先进入编译出vmlinux的kernel文件夹
gdb-multiarch vmlinux
(gdb) target remote :1234 ==》连接上qemu的端口
Remote debugging using :1234
0x0000000040000000 in ?? ()
(gdb) b start_kernel ==》设置断点
(gdb) c ==》运行到断点
(gdb) p /x kimage_voffset ==》查看镜像地址
$3 = 0xffff80003fe00000
```

获取完成之后crash:

```
NOTE: setting kimage_voffset to: 0xffff7fffd0000000

crash> bt
```

如果是通过加载ko模块的进行测试的, 在crash命令行下输入:

```
mod -s kdump /kdump/demo/stack/kdump.ko
mod -s <模块的名字, lsmod就知道了> <ko的文件>
```
